SYSTEM AND METHOD FOR INTELLIGENT, GLOBALLY DISTRIBUTED NETWORK STORAGE

BACKGROUND OF THE INVENTION

1. Field of the Invention.

The present invention relates, in general, to network data storage, and, more particularly, to software, systems and methods for intelligent management of globally distributed network storage.

Relevant Background.

political, and social power are Economic, increasingly managed by data. Transactions and wealth are Political power is analyzed and represented by data. modified based on data. Human interactions and relationships are defined by data exchanges. Hence, the efficient distribution, storage, and management of data is expected to play an increasingly vital role in human society.

The quantity of data that must be managed, in the form of computer programs, databases, files, and the like, increases exponentially. As computer processing power increases, operating system and application software becomes larger. Moreover, the desire to access larger data sets such as data sets comprising multimedia files and large databases further increases the quantity of data that is managed. This increasingly large data load must be transported between computing devices and stored in an accessible fashion. The exponential growth rate of data

10

15

20

25

30

is expected to outpace improvements in communication bandwidth and storage capacity, making the need to handle data management tasks using conventional methods even more urgent.

flavors. varieties and many Data comes in include, example, the for of data Characteristics frequency of read access, frequency of write access, size of each access request, permissible latency, permissible availability, desired reliability, security, and the like. Some data is accessed frequently, yet rarely changed. Other data is frequently changed and requires low latency These characteristics should affect the manner in which data is stored.

Many factors must be balanced and often compromised in the operation of conventional data storage systems. Because the quantity of data stored is large and rapidly increasing, there is continuing pressure to reduce cost per bit of storage. Also, data management systems should be sufficiently scaleable to contemplate not only current needs, but future needs as well. Preferably, storage systems are designed to be incrementally scaleable so that a user can purchase only the capacity needed at any High reliability and high availability particular time. are also considered as data users become increasingly unavailable intolerant of lost, damaged, and Unfortunately, conventional data management architectures must compromise these factors -- no single data architecture reliable, cost-effective, highly provides а solution. scaleable available, and dynamically Conventional RAID (redundant array of independent disks) systems provide a way to store the same data in different places (thus, redundantly) on multiple storage devices By placing data on multiple disks, such as hard disks.

10

15

20

25

30

input/output (I/O) operations can overlap in a balanced improving performance. Since using multiple disks increases the mean time between failure (MTBF) for the system as a whole, storing data redundantly also increases A RAID system relies on a hardware or fault-tolerance. software controller to hide the complexities of the actual data management so that a RAID systems appear single logical hard disk. operating system to be a However, RAID systems are difficult to scale because of physical limitations on the cabling and controllers. Also, RAID systems are highly dependent on the controllers so that when a controller fails, the data stored behind becomes unavailable. controller Moreover, specialized, systems require rather than commodity hardware, and so tend to be expensive solutions.

RAID solutions are also relatively expensive maintain. RAID systems are designed to enable recreation of data on a failed disk or controller but the failed disk must be replaced to restore high availability and high reliability functionality. Until replacement occurs, the vulnerable to additional device failures. is system the system hardware must be continually Condition of monitored and maintenance performed as needed to maintain functionality. Hence, RAID systems must be physically situated so that they are accessible to trained technicians who can perform the maintenance. limitation makes it difficult to set up a RAID system at a remote location or in a foreign country where suitable technicians would have to be found and/or transported to the RAID equipment to perform maintenance functions.

NAS (network-attached storage) refers to hard disk storage that is set up with its own network address rather than being attached to an application server. File

15

30

requests are mapped to the NAS file server. NAS may perform I/O operations using RAID internally (i.e., within a NAS node). NAS may also automate mirroring of data to one or more other NAS devices to further improve fault tolerance. Because NAS devices can be added to a network, they may enable some scaling of the capacity of the storage systems by adding additional NAS nodes. However, NAS devices are constrained in RAID applications to the abilities of conventional RAID controllers. NAS systems do not generally enable mirroring and parity across nodes, and so a single point of failure at a typical NAS node makes all of the data stored at that NAS node unavailable.

The inherent limitations of RAID and NAS storage make it difficult to strategically locate data storage mechanisms. Data storage devices exist in a geographic, political, economic and network topological context. Each of these contexts affects the availability, reliability, security, and many other characteristics of stored data.

The geographic location of any particular storage device affects the cost of installation, operation 20 Moreover, geographic location affects and maintenance. how quickly and efficiently the storage device can be deployed, maintained, and upgraded. Geographic location also affects, for example, the propensity of disasters such as earthquakes, hurricanes, tornadoes, and 25 the like that may affect the availability and reliability of stored data.

relate and economic contexts the Political to underlying socioeconomic and political constraints that society places on data. The cost to implement network storage varies significantly across the Inexpensive yet skilled labor is available in locations to set up and maintain storage. Network access

15

20

25

30

is expensive in some locations. Tax structures may tax data storage and/or transport on differing bases that affect the cost of storage at a particular location. Governments apply dramatically different standards and example, with respect to data. For one policies data unrestricted storage may allow jurisdiction representing any type of program or user data. jurisdictions may restrict certain types of data (e.g., disallow encrypted data or political criticism).

The network topological context of stored data refers to the location of the data storage device with respect to other devices on a network. In general, latency (i.e., the amount of time it takes to access a storage device) is affected by topological closeness between the device requesting storage and the storage device itself. The network topological context may also affect which devices can access a storage device, because mechanisms such as firewalls may block access based on network topological criteria.

The strategic location of data storage refers to the process of determining a location or locations for data storage that provide a specified degree of availability, reliability, and security based upon the relevant contexts associated with the data storage facilities. Current data storage management capabilities do not allow a data user automatically select or change the location locations at which data is stored. Instead, a data storage center must be created at or identified within a desired location at great expense in time and money. requires detailed analysis by the data user of locations that meet the availability, reliability, and security criteria desired -- an analysis that is often difficult if not impossible. The data storage center must then be

10

15

20

25

supported and maintained at further expense. A need exists for a data storage management system that enables data users to specify desired performance criteria and that automatically locates data storage capacity that meets these specified criteria.

way data conventionally Philosophically, the is managed is inconsistent with the hardware devices and infrastructures that have been developed to manipulate and For example, computers are transport data. characteristically general-purpose machines that are perform a virtually unlimited readily programmed to In large part, however, computers variety of functions. are loaded with a fixed, slowly changing set of data that limits their general-purpose nature to make the machines special-purpose. Advances in processing speed, peripheral performance and data storage capacity are most dramatic in commodity computers and computer components. data storage solutions cannot take advantage of these advances because they are constrained rather than extended by the storage controllers upon which they are based. Similarly, the Internet was developed as a fault tolerant, However, network resources multi-path interconnection. are conventionally implemented in specific network nodes failure of the node makes the resource such that unavailable despite the fault-tolerance of the network to which the node is connected. Continuing needs exist for highly available, highly reliable, and highly scaleable data storage solutions.

SUMMARY OF THE INVENTION

30 Briefly stated, the present invention involves a data storage system that enables intelligent distribution of data across a plurality of storage devices. The plurality

15

20

of storage devices forms a "storage substrate" upon which the present invention operates. Each of the storage devices is associated with one or more attributes that characterize the context of the storage device (e.g., capacity, location, connectivity, and the like). Storage tasks are associated with a set of criteria that define desired storage characteristics such as cost, location, security, availability, network connectivity, and the like. Storage devices for a specific storage task are selected by matching the attributes associated with available storage devices to the desired set of criteria.

In a particular implementation, a data storage system is provided that includes a plurality of storage nodes, where each node exists at a physical location having one or more contexts. Interface mechanisms couple to each storage node to communicate storage access requests with the storage node. Data storage management processes select one or more of the storage nodes to serve a data storage request based at least in part upon the particular contexts associated with each of the storage nodes.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is directed to a globally distributed data storage system and a method for managing and using such a system. The system and method of the invention endeavor to optimize the storage contained in a diverse collection of network-accessible It optimizes access based on geography, storage nodes. interconnectedness, redundancy, bandwidth, latency, expense, security, reliability and/or other attributes the physical location associated with characteristics of the storage devices. invention associates requirements placed on the data with desired criteria, then selects sets of or more aggregate storage capacity having contexts that together The contexts are represented and satisfy the criteria. communicated by the dynamic exchange of state information between the storage nodes. Preferably, the invention is implemented to enable migration of data fluidly within the network of storage devices to maintain dynamic compliance with the set of desired criteria.

The present invention is illustrated and described in terms of a distributed computing environment such as an enterprise computing system using public communication channels such as the Internet. However, an important feature of the present invention is that it is readily scaled upwardly and downwardly to meet the needs of a

10

20

25

30

particular application. Accordingly, unless specified to the contrary, the present invention is applicable to significantly larger, more complex network environments as well as small network environments such as conventional LAN systems.

In the example of FIG. 1, sites 101-105 are globally distributed storage nodes, each implementing a quantity of Each site 101-105 network accessible mass storage. implements one or more than one storage node where each storage node is identified by an independent network Site 101 provides address and so is network accessible. highly connected, high speed, but relatively high cost is readily maintained and highly Site 101 storage. available, but may be too expensive to house seldom used, 15 replicated, or backup data. Site 102 represents a high capacity, low cost storage facility. Site 103 illustrates a highly secure, relatively expensive storage facility located on the east cost of the United States. sites 101-103 are subject to jurisdiction of the United individually subject to and each is jurisdiction of the various states, counties, cities or other municipalities in which they are physically located.

Site 104 represents a geographically remote, low cost While low cost, the geographic facility. remoteness of site 104 may increase maintenance costs and level of network connectivity and imply a lower Site 105 illustrates a poorly connected availability. storage site located in an alternative jurisdiction that Sites 104 and 105 may provide inexpensive overhead costs. are subject to the laws and customs associated with their physical locations, which are different than associated with sites 101-103. Free speech customs and laws in the various jurisdictions, for example, may affect

10

15

20

25

30

the types of data that can be stored at any Data storage and transport as well as network location. be taxed orotherwise regulated connectivity may Even within the United differently between jurisdictions. States, as represented by storage nodes 101-103, varying state jurisdictions may subject the data owner and/or data to varying state court jurisdictions and their associated regulatory requirements.

enables mechanism invention a The present strategically select the storage location or locations varying for a specific task based on the characteristics associated with these locations. example, a primary image of a frequently accessed data volume is suitable for site 101. Site 102 may be more for personal computer backup data--where appropriate access is less frequent, but volume is large due to a Site 103 may be appropriate for large number of users. financial records or medical data where highly secure storage is required. Because of the lower cost associated with site 104, it may be appropriate for storing backup or replicated data images of data stored on sites 101-103, Site 105 may be appropriate for storing for example. seldom used archival records. All of these examples are illustrative only, as it is contemplated that every data storage need will have its own set of desired performance characteristics that will be satisfied by one, and often more than one data storage location.

The present invention is directed to data storage on a network 201 shown in FIG. 2. FIG. 2 shows an exemplary internetwork environment 201 such as the Internet. The Internet is a global internetwork formed by logical and physical connection between multiple Wide Area Networks (WANs) 203 and Local Area Networks (LANs) 204. An

10

15

20

25

30

Internet backbone 202 represents the main lines routers that carry the bulk of the traffic. The backbone is formed by the largest networks in the system that are operated by major Internet service providers (ISPs) such and America Online, Sprint, UUNet, MCI, While single connection lines are used example. conveniently illustrate WAN 203 and LAN 204 connections to the Internet backbone 202, it should be understood that in reality multi-path, routable wired or wireless connections exist between multiple WANs 203 and LANs 204. This makes an internetwork 201 such as the Internet robust when faced with single or multiple failure points.

important to distinguish network connections It is from internal data pathways implemented between peripheral devices within a computer. A "network" comprises a system of general purpose, usually switched, physical connections that enable logical connections between processes The physical connections operating on nodes 105. implemented by a network are typically independent of the logical connections that are established between processes In this manner, a heterogeneous set of using the network. processes ranging from file transfer, mail transfer, and the like can use the same physical network. Conversely, the network can be formed from a heterogeneous set of physical network technologies that are invisible to the logically connected processes using the network. the logical connection between processes implemented by a physical network of the connection, is independent internetworks are readily scaled to a virtually unlimited number of nodes over long distances.

In contrast, internal data pathways such as a system bus, Peripheral Component Interconnect (PCI) bus, Intelligent Drive Electronics (IDE) bus, Small Computer

15

20

25

30

System Interface (SCSI) bus, Fibre Channel, and the like define physical connections that implement special-purpose connections within a computer system. These connections implement physical connections between physical devices as opposed to logical connections between processes. These physical connections are characterized by limited distance between components, limited number of devices that can be coupled to the connection, and constrained format of devices that can be connected over the connection.

discussion, To generalize the above the "network" as it is used herein refers to a means enabling a physical and logical connection between devices that 1) enables at least some of the devices to communicate with the devices external sources, and 2) enables communicate with each other. It is contemplated that some of the internal data pathways described above could be modified to implement the peer-to-peer style communication of the present invention, however, such functionality is in commodity available components. currently Moreover, such modification, while useful, would fail to realize the full potential of the present invention as storage nodes implemented across, for example, a SCSI bus would inherently lack the level of physical and topological diversity that can be achieved with the present invention.

Referring again to FIG. 1, the present invention is implemented by placing storage devices at nodes 105. storage at any node 105 may comprise a single hard drive, such may comprise a managed storage system conventional RAID device having multiple hard configured as a single logical volume, or may comprise any configuration reasonable hardware in-between. Significantly, the present invention manages redundancy

10

15

20

25

operations across nodes, as opposed to within nodes, so that the specific configuration of the storage within any given node can be varied significantly without departing from the present invention.

Optionally, one or more nodes such as nodes 106 implement storage allocation management (SAM) processes that manage data storage across multiple nodes 105 in a distributed, collaborative fashion. SAM processes may be centralized fashion within in a implemented purpose nodes 106. Alternatively, SAM processes implemented within some or all of RAIN nodes 105. processes communicate with each other and handle access to the actual storage devices within any particular RAIN node The capabilities, distribution, and connections provided by the RAIN nodes in accordance with the present invention enable storage processes (e.g., SAM processes) to operate with little or no centralized control for the system as whole.

nodes 207 implement such as more nodes One intelligent management processes in accordance with the present invention--indicated as iRAIN processes 502 5--that communicate with SAM processes 506 orchestrate data storage. The iRAIN processes centralized fashion within implemented in a purpose nodes 207. Alternatively, iRAIN processes may be implemented within some or all of RAIN nodes 205/206. iRAIN processes communicate with SAM processes 206 access state information about the individual contexts associated with the collection of RAIN storage nodes 505.

30 The network of storage nodes that in cooperation with SAM processes orchestrate read and write tasks amongst the nodes, together form what is referred to herein as a "storage substrate". The intelligent management processes

15

20

25

30

of the present invention operate to direct and constrain the operations of the storage substrate so as to satisfy desired criteria specified for a particular storage task. Like the SAM processes discussed above, the intelligent management processes may be implemented in a centralized fashion in a single storage node or in a small number of storage nodes 205. Alternatively, these intelligent management processes may be implemented in all storage nodes 205.

FIG. shows an alternate view of an exemplary which environment in the present computing invention is implemented. Internetwork 201 enables the of interconnection a heterogeneous set of devices and mechanisms ranging from a supercomputer or data center 301 to a hand-held or pen-based device 306. While such devices have disparate data storage needs, they share an ability to access data via network 201 and operate on that data with their own resources. Disparate computing devices including mainframe computers (e.g., VAX station 302 and IBM AS/400 station 308) as personal computer or workstation class devices such as IBM compatible device 303, Apple Macintosh device 304 and laptop computer 305 are readily interconnected via internetwork 201.

Internet-based network 313 comprises a set of logical connections, some of which are made through internetwork between a plurality of internal networks Conceptually, Internet-based network 313 is akin to a WAN that it enables logical connections spatially distant nodes. Internet-based networks 313 may implemented using the Internet or other public and private WAN technologies including leased lines, Fibre Channel, and the like.

10

15

20

25

30

Similarly, internal networks 214 are conceptually akin to LANs 104 shown in FIG. 1 in that they enable logical connections across more limited distances than those allowed by a WAN 103. Internal networks 214 may be implemented using LAN technologies including Ethernet, Fiber Distributed Data Interface (FDDI), Token Ring, Appletalk, Fibre Channel, and the like.

Each internal network 214 connects one or more RAIN elements 215 to implement RAIN nodes 105. Each RAIN element 215 comprises a processor, memory, and one or more mass storage devices such as hard disks. RAIN elements also include hard disk controllers that conventional EIDE or SCSI controllers, or may be managing controllers such as RAID controllers. RAIN elements 215 may be physically dispersed or co-located in one or more racks sharing resources such as cooling and power. Each node 105 is independent of other nodes 105 in that failure not affect or unavailability of one node 105 does availability of other nodes 105, and data stored on one node 105 may be reconstructed from data stored on other nodes 105.

The perspective provided by Fig. 2 is highly physical and it should be kept in mind that physical implementation of the present invention may take a variety of forms. The multi-tiered network structure of Fig. 2 may be altered to a single tier in which all RAIN nodes 105 communicate directly with the Internet. Alternatively, three or more network tiers may be present with RAIN nodes 105 clustered behind any given tier. A significant feature of the present invention is that it is readily adaptable to these heterogeneous implementations.

The specific implementation discussed above is readily modified to meet the needs of a particular -15-

10

15

20

25

30

application. Because the present invention uses network methods to communicate with the storage nodes, the particular implementation of a storage node is largely hidden from the devices accessing the storage nodes, uniquely receptive invention the present node configuration. For example, in modifications processor type, speed, instruction set architecture, and the like can be modified easily and may vary from node to The hard disk capacity and configuration within RAIN elements 315 can be readily increased or decreased to meet the needs of a particular application. Although mass storage is implemented using magnetic hard disks, other types of mass storage devices such as magneto-optical, optical disk, digital optical tape, holographic storage, atomic force probe storage and the like can be used interchangeably as they become increasingly available. Memory configurations including but not limited to RAM capacity, RAM speed, and RAM type (e.g., DRAM, SDRAM) can vary from node to node making the present invention incrementally upgradeable to take advantage of new technologies and component pricing. Network interface components may be provided in the form of expansion cards coupled to a mother board 405 or built into a motherboard 405 and may operate with a variety of available interface BaseT Ethernet, 100 BaseT Ethernet, speeds (e.g., 10 Gigabit Ethernet, 56K analog modem) as well as provide varying levels of buffering and the like.

Specifically, it is contemplated that the processing power, memory, network connectivity and other features of the implementation shown in Fig. 4 could be integrated within a disk drive controller and actually integrated within the housing of a disk drive itself. In such a configuration, a RAIN element 315 might be deployed simply by connecting such an integrated device to an available

10

15

20

25

30

network, and multiple RAIN elements 315 might be housed in a single physical enclosure.

Each RAIN element 315 may execute an particular implementations use a system. The operating system (OS) or UNIX-variant OS such as Linux. It is contemplated, however, that other operating systems including DOS, Microsoft Windows, Apple Macintosh OS, NTand the like may be Microsoft Windows os/2, equivalently substituted with predictable changes in lightweight performance. Moreover, special purpose operating systems or micro kernels may also be used, although cost of development of such operating systems may The operating system chosen implements a be prohibitive. platform for executing application software and processes, mechanisms for accessing a network, and mechanisms for accessing mass storage. Optionally, the OS supports a storage allocation system for the mass storage via the hard disk controller(s).

In the particular embodiment there is no centralized storage controller required within a node 205 nor is a centralized storage controller required for a group of nodes 205 connected via an internal network 314. This ensures that each node 205 (i.e., each RAIN element 315) operates independently. Conceptually, storage management is provided across an arbitrary set of nodes 205 that may be coupled to separate, independent internal networks 315 via internetwork 313. This increases availability and reliability in that one or more internal networks 314 can fail or become unavailable due to congestion or other events without affecting the availability of data.

Various application software and processes can be implemented on each RAIN element 315 to provide network connectivity via a network interface 404 using appropriate

10

15

20

25

30

network protocols such as User Datagram Protocol (UDP), Transmission Control Protocol (TCP), Internet Protocol (IP), Token Ring, Asynchronous Transfer Mode (ATM), and the like.

In the particular embodiments, the data stored in any particular node 205 can be recovered using data at one or more other nodes 205 using data recovery and storage These data recovery and storage management processes. management processes preferably execute on a node 206 the nodes 205 separate from the and/or on one of upon which the data is particular node 205 Conceptually, storage management capabilities are provided across an arbitrary set of nodes 205 that may be coupled separate, independent internal networks 315 via 313. This increases availability and internetwork reliability in that one or more internal networks 314 can fail or become unavailable -- due to congestion, changes in network topology, or other events -- without affecting the availability of data.

In an elemental form, each RAIN element 315 has some superficial similarity to a network attached storage (NAS) However, because the RAIN elements 315 work cooperatively, the functionality of а comprising multiple cooperating RAIN elements significantly greater than a conventional NAS RAIN element preferably supports Further, each structures that enable read, write, and parity operations across nodes 205 (as opposed to within nodes 205). data structures enable operations akin to RAID operations because RAIN operations are distributed across nodes and the nodes are logically, but not necessarily physically connected. For this reason, RAIN read, write, and parity significantly more fault tolerant, operations are

15

20

25

30

reliable, and efficient than those operations as enabled by conventional RAID systems.

Fig. 5 shows a conceptual diagram of the relationship between the intelligent storage management processes in labeled "iRAIN" accordance with the present invention, processes 502 in Fig. 5, with the underlying storage substrate implemented by SAM processes 506 on storage It should be understood that RAIN nodes 505, nodes 505. SAM processes 506, and iRAIN processes 502 are preferably distributed processes that perform system operations in In other words, the physical machines that parallel. implement these processes may comprise tens, hundreds, or thousands of machines that communicate with each other via network(s) 201 in a highly parallellized manner to perform storage tasks.

A collection of RAIN storage elements 505 provides by accepting basic persistent data storage functions read/write commands from external sources. Additionally, RAIN storage elements communicate with each other exchange state information that describes, for example, the particular context of each RAIN element 315 within the collection 505.

A collection of SAM processes 506 provides basic storage management functions using the collection of RAIN storage nodes 505. The collection of SAM processes 506 is implemented in a distributed fashion across multiple nodes SAM processes 506 receive storage 205/206. requests, and generate corresponding read/write commands to members of the RAIN node collection 505. SAM processes in the particular implementations, akin to RAID processes in that they select particular RAIN nodes 315 to provide a desired level of availability, reliability, redundancy, and security using a variety of parity storage

10

15

20

25

30

schemes. SAM processes 506 provide a first level of data management, but in general do not select particular storage nodes 315 for a particular task based on context information.

iRAIN processes 502, however, compare desired associated with a storage task with state criteria information describing the context of particular RAIN nodes 315 within a collection 505 to direct and constrain the SAM processes 506. The collection of iRAIN processes in a distributed fashion across is implemented The iRAIN processes 502 are multiple nodes 205/206/207. from clients receive storage tasks coupled to storage involve allocation, Storage tasks may deallocation, and migration, as well as read/write/parity associated with Storage tasks are operations. specification of desired criteria that the storage task For example, a storage task may be should satisfy. associated with one or more criteria such as cost, availability, jurisdictional, or security criteria. operation, iRAIN processes 501 direct and constrain the operations of the storage substrate to satisfy the desired criteria specified by a particular storage task.

Fig. 6 illustrates an exemplary set of intelligent management processes 501. These intelligent management processes include processing requests for storage access, identification and allocation or deallocation of storage capacity, migration of data between storage nodes 205, redundancy synchronization between redundant data copies, Other processes include monitoring the and the like. political, economic, and topological contexts of each storage node 205, generating storage tasks that reflect contexts, changing and the like. The processes 502 preferably abstract or hide the underlying

15

configuration, location, cost, and other context information associated with each RAIN node 205 from data users. The iRAIN processes 501 also enable a degree of fault tolerance that is greater than any storage node in isolation as parity is spread out across multiple storage nodes that are geographically, politically and topologically dispersed depending on the desired criteria.

As shown in Fig. 6, an interface or protocol 604 is used for requesting services or servicing requests from clients 501, and for exchanging requests between iRAIN processes 501, SAM processes 506, and storage nodes 505. This protocol can be used between processes executing on a is more commonly used between nodes single node, but distributed across a network, typically the Internet. Storage access requests indicate, for example, the type and size of data to be stored, characteristic frequency of and write access, constraints of physical topological locality, cost constraints, and similar data that indicate desired data storage criteria.

The iRAIN processes associate the desired criteria 20 with a storage request or a storage task as discussed The iRAIN processes 502 generate storage hereinbefore. requests to SAM processes 506 and/or storage nodes 505 to implement the actual storage tasks. In generating these iRAIN processes 502 use the desired storage requests, 25 criteria to select which storage nodes exist in contexts that satisfy the desired criteria. The current context of the storage nodes is represented by state information held in the state information data structure 503.

The connection between a storage task and the desired criteria associated with that task is preferably persistent in that the desired criteria remain associated with the data for the lifetime of the data stored. This

10

15

20

25

30

persistence enables the iRAIN processes 502 to periodically, continuously, or intermittently check ensure that a storage task's desired criteria are being satisfied by the current context of the nodes in which the It is contemplated that over time the data is stored. desired criteria for a particular task may change, or the contexts of the various storage nodes will change, or Such changes can be detected by the iRAIN processes 502 by comparing the desired criteria associated with data to the current state information.

When changes result in a set of data stored in a is no longer consistent with the desired manner that associated with it, the iRAIN process criteria generate storage requests (e.g., read/write operations) to SAM processes 506 and/or RAIN nodes 505 that effect migration of data to storage devices having contexts that satisfy the desired criteria. Changes can be detected proactively described above, orreactively, as information in the state including anticipatory state information data structure. For example, an impending hurricane may reduce the reliability and availability contexts associated with storage nodes in the hurricane's IRAIN processes 501, when informed of changes in path. this state information, can proactively move data from storage nodes in the hurricane's path before the event actually affects availability.

SAM processes 506 also include processes to implement high availability, high reliability data storage such as that implemented by conventional RAID systems. In one embodiment, the system in accordance with the present invention defines multiple levels of RAID-like fault tolerant performance across nodes in addition to fault tolerant functionality within nodes. The HA/HR processes

10

15

20

25

30

also include methods to recreate data in the event of component failure and to redirect requests for data access to available storage nodes 105 in the event of failure, congestion, or other events that limit data availability. Redundancy synchronization processes manage storage capacity that is configured having mirrored or parity copies to ensure that all read and write operations are mirrored to all copies and/or parity data is computed, stored, and/or checked and verified in conjunction with read/write accesses.

processes include processes for Allocation aggregation of node storage to present a single collective storage resource, and allocation of the aggregated storage to match performance criteria specified in the request for data storage access. Storage capacity in each storage node is characterized by such attributes as access speed, transfer rate, network locality (i.e., network topological context), physical locality, interconnectedness, security, reliability, political domain, cost, or other attributes the geographic, useful in discriminating jurisdictional and topological differences political, between storage nodes 105. Allocation table 502 includes a set of metadata describing these attributes for some or all available RAIN elements 315. SAM allocation processes analyze the desired performance characteristics associated with the data and allocate capacity within a set of RAIN elements 315 that satisfy, or closely satisfy, these specified performance criteria.

In this manner, the intelligent storage management solution in accordance with the present invention enables the specifics of a data storage task to be separated from a wide variety of data access concerns. The present invention enables the dynamic configuration and selection

15

of where data is stored, how fault tolerantly it is stored, the dynamic adjustment of the housing of data to minimize costs, and maximizing the availability of the data. The present invention also enables the movement of data closer to its users or consumers and automatic adaptation to networking conditions or new network topologies. Moreover, the present invention provides a system and methods that enable data migration that remains compliant with changing jurisdictional, political and social requirements.

Although the invention has been described and illustrated with a certain degree of particularity, it is understood that the present disclosure has been made only by way of example, and that numerous changes in the combination and arrangement of parts can be resorted to by those skilled in the art without departing from the spirit and scope of the invention, as hereinafter claimed.
